Abstract

Many studies have been carried out in order to increase the search efficiency of constraint satisfaction problems; among them, some make use of *structural* properties of the constraint network; others take into account *semantic* properties of the constraints, generally assuming that *all* the constraints possess the given property. In this paper, we propose a new decomposition method benefiting from both semantic properties of *functional* constraints (not *bijective* constraints) and structural properties of the network; furthermore, not all the constraints need to be functional. We show that under some conditions, the existence of solutions can be guaranteed. We first characterize a particular subset of the variables, which we name a *root set*. We then introduce *pivot consistency*, a new local consistency which is a weak form of path consistency and can be achieved in $O(n^2d^2)$ complexity (instead of $O(n^3d^3)$ for path consistency), and we present associated properties; in particular, we show that any consistent instantiation of the root set can be linearly extended to a solution, which leads to the presentation of the aforementioned new method for solving by decomposing functional CSPs.

1. Introduction

Improving search efficiency is one of the main goals of artificial intelligence. Efficiency is particularly important for researchers interested in constraint satisfaction problems (CSPs), also called *constraint networks*. In order to achieve this aim, various approaches have been tried, such as filtering techniques (mainly arc and path consistencies) (Montanari, 1974; Mackworth, 1977; Mohr & Henderson, 1986; Bessière, 1994) or improvements to the backtrack process (Haralick & Elliot, 1980; Dechter & Pearl, 1988; Ginsberg, 1993; Prosser, 1993). Other work concerned the characterization of classes of polynomial problems, based on the size of their domains (Dechter, 1992) or on the structure of the constraint network (Freuder, 1978), leading to the presentation of decomposition methods such as the *cycle-cutset* (Dechter, 1990) or the *tree clustering* (Dechter & Pearl, 1989) methods. A more recent approach consists of taking into account *semantic* properties of the constraints (as opposed to *structural* or *topological* properties of the network) to achieve arc consistency efficiently for specific classes of constraints (Van Hentenryck, Deville, & Teng, 1992; Mohr & Masini, 1988), or to characterize some tractable classes of problems (van Beek, 1992; van Beek & Dechter, 1994; Kirousis, 1993; Cooper, Cohen, & Jeavons, 1994). We present these results further in this paper.

Some frequently encountered constraints are *functional* constraints, for instance in peptide synthesis (Janssen, Jégou, Nouguier, Vilarem, & Castro, 1990) or in Constraint Logic

Programming (Van Hentenryck et al., 1992). Many constraint-based systems and languages use functional constraints, including THINGLAB (Borning, 1981), GARNET (Myers, Giuse, & Vander Zanden, 1992) and KALEIDOSCOPE (Freeman-Benson & Borning, 1992).

In this paper, we study functional constraints: the relations they represent are partial functions (notice those are *not* the same as *bijective* constraints: see sections 2.1 and 2.2). More precisely, we study the properties given to them by a new local consistency, *pivot consistency*. We notably show that, under some conditions, this local consistency guarantees the existence of solutions and makes them easier to find: first, we characterize a subset of the variables, called a *root set* and denoted \mathcal{R} ; we then show that if the network is pivot consistent, then any consistent instantiation of \mathcal{R} can be linearly extended to a solution, provided the instantiation order is \mathcal{R} -compatible (*i.e.*, it possesses some topological properties associated with \mathcal{R} and the functional constraints).

We then introduce a new method for solving any functional CSP by decomposing it into two subproblems: first, finding a consistent instantiation of the root set, and second, extending this partial instantiation to a solution (in a backtrack-free manner).

The main difficulty is clearly to find a consistent instantiation of the root set, which remains exponential in its size. The method we present here is therefore all the more efficient since the root set is of small size.

Another aspect we wish to point out is that, unlike most of the work dealing with constraints which possess some specific properties, this method not only applies when *all* the constraints possess the given property (or properties), but also when only *some* of them do.

This paper is organized as follows: section 2 first introduces the basic definitions and notations regarding CSPs which will be used in the following. We then define functional constraints and discuss previous work and its relations with this paper. The last part of the section presents notions associated with functional constraints, which are mainly found in graph theory. We then introduce pivot consistency and an $O(n^2d^2)$ algorithm allowing to achieve the latter in section 3, before presenting in section 4 the properties supplied to a CSP by this consistency. We finally propose a method based on those properties for solving CSPs composed of functional constraints (with or without additional non-functional constraints).

2. Preliminaries

Definition 2.1 A binary CSP \mathcal{P} is defined by (X, D, C, R) , where

- $X = \{x_1, x_2, \dots, x_i, \dots, x_n\}$ is the set of its n variables.
- $D = \{D_1, \dots, D_i, \dots, D_n\}$ is the set of its n domains, where each $D_i = \{a_i, b_i, \dots\}$ is the set of the possible values for variable x_i ; the size of the largest domain of D is called d .
- C is the set of its e constraints $\{C_1, \dots, C_k, \dots, C_e\}$; for the sake of simplicity, a constraint $C_k = \{x_i, x_j\}$ involving variables x_i and x_j is denoted C_{ij} .
- R is the set of the e relations associated with the constraints, where the relation R_{ij} is the subset of the Cartesian product $D_i \times D_j$ specifying the pairs of mutually compatible values.

A graph $\mathcal{G} = (X, C)$ called the *constraint graph* can be associated with \mathcal{P} , where the vertices and the edges (or arcs) respectively represent the variables and the constraints. Another graph, representing the relations of the CSP, can also be defined: the *consistency graph*. Figure 1 represents the constraint and consistency graphs of the following example:

A travel agency offers five destinations to its customers: Paris, London, Washington, New-York and Madrid, and employs three guides to accompany them: Alice, Bob and Chris. These guides provide the information below:

- *Alice wishes to go to Paris or New-York, but she only speaks French.*
- *Bob speaks English and French, and does not want to go to Madrid (but accepts any other city).*
- *Chris only speaks Spanish, and refuses to go to any city but New-York.*

The manager would like to find all the possibilities left to him, i.e., which guide he can send to which city, with which currency, knowing that each guide must of course speak the language of the country he (or she) visits, and the currency must be that of the country.

This problem can be encoded by the CSP \mathcal{P}_{ex} , composed of five variables and five constraints:

- The set of the five variables is
 $X = \{GUIDES, CITIES, COUNTRIES, CURRENCIES, LANGUAGES\}$

- Their five domains are:
 $D_{GUIDES} = \{Alice (A), Bob (B), Chris (C)\}$
 $D_{CITIES} = \{Paris, London, Washington, New-York, Madrid\}$
 $D_{COUNTRIES} = \{France, GB, USA, Spain\}$
 $D_{CURRENCIES} = \{FrF, £, \$, Pes\}$
 $D_{LANGUAGES} = \{French, English, Spanish\}$

- The set of the five constraints is:

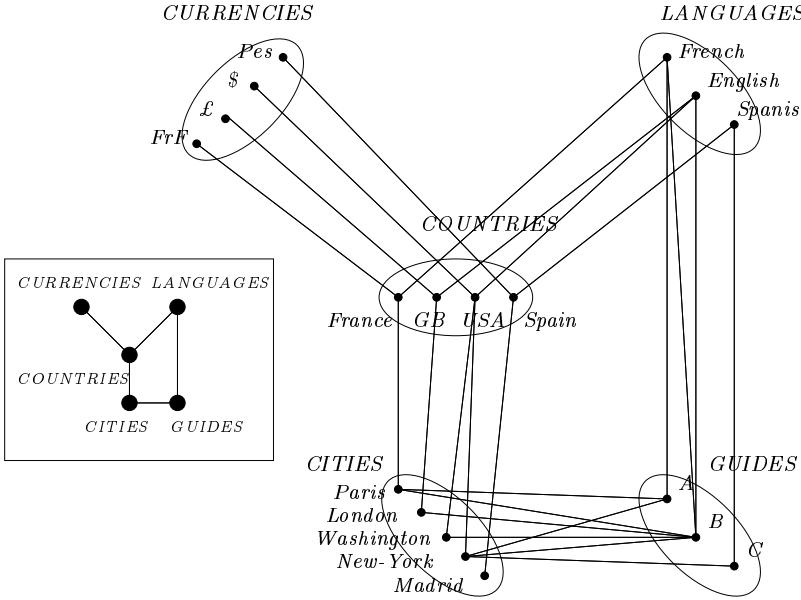

$$C = \{C_{GUIDES-CITIES}, C_{CITIES-COUNTRIES}, C_{GUIDES-LANGUAGES}, \\ C_{COUNTRIES-CURRENCIES}, C_{COUNTRIES-LANGUAGES}\}$$

where these constraints respectively represent the cities the guides wish (or accept) to visit, the countries the cities belong to, the languages spoken by the guides, the currencies used in the countries, and the official languages of the countries. Notice there is no explicit constraint between the currencies and the guides: this constraint will be induced by the cities (and thus the countries) visited by the guides on the one hand, and by the currencies of the countries on the other hand.

- The five associated relations are:

$$R_{GUIDES-CITIES} = \{(Alice, Paris), (Alice, New-York), (Bob, Paris), (Bob, London), \\ (Bob, Washington), (Bob, New-York), (Chris, New-York)\}$$

$$R_{GUIDES-LANGUAGES} = \{(Alice, French), (Bob, French), (Bob, English), \\ (Chris, Spanish)\}$$

Figure 1: Constraint graph and Consistency graph of \mathcal{P}_{ex}

$$R_{CITIES-COUNTRIES} = \{(Paris, France), (London, GB), (Washington, USA), (New-York, USA), (Madrid, Spain)\}$$

$$R_{COUNTRIES-CURRENCIES} = \{(France, FrF), (GB, £), (USA, \$), (Spain, Pes)\}$$

$$R_{COUNTRIES-LANGUAGES} = \{(France, French), (GB, English), (USA, English), (Spain, Spanish)\}$$

If there is no constraint between variables x_i and x_j ($c_{ij} \notin C$), all pairs of values are therefore allowed: $R_{ij} = D_i \times D_j$. R_{ij} is then called a *universal relation*.

The notion of *support* is related to the pairs that belong or not to the relations: we say that a value $a_k \in D_k$ is a *support* of (or supports) a value $a_i \in D_i$ for the constraint c_{ik} if and only if $(a_i, a_k) \in R_{ik}$. Also, the value $a_k \in D_k$ is a support of the pair $(a_i, a_j) \in R_{ij}$ if and only if a_k both supports a_i for the constraint c_{ik} and a_j for the constraint c_{jk} .

Y stands for any subset of X , and Y_k represents the set of the first k variables of X , w.r.t. an order explained in the context. The default order will be $x_1, x_2, \dots, x_{n-1}, x_n$. Also, the order for \mathcal{P}_{ex} will be *GUIDES, CITIES, COUNTRIES, CURRENCIES, LANGUAGES*.

Given $Y_t = \{x_1, \dots, x_t\}$ a subset of X , the assignment to each variable x_i of Y_t of a value a_i of D_i is called a *(partial) instantiation* of Y_t . Such an instantiation $I_t = (a_1, \dots, a_i, \dots, a_j, \dots, a_t)$ is consistent if and only if every constraint included in Y_t is satisfied; formally, $\forall i, j \leq t$ s.t. $c_{ij} \in C$, $(a_i, a_j) \in R_{ij}$. For instance, neither *(Alice, London)* nor *(Bob, Paris, Spain)* are consistent, whereas *(Alice, Paris)* and *(Chris, New-York, Peseta, Spanish)* both are. A *solution* is therefore defined as a consistent instantiation of X . A solution to X is thus *(Alice, Paris, France, FrF, French)*.

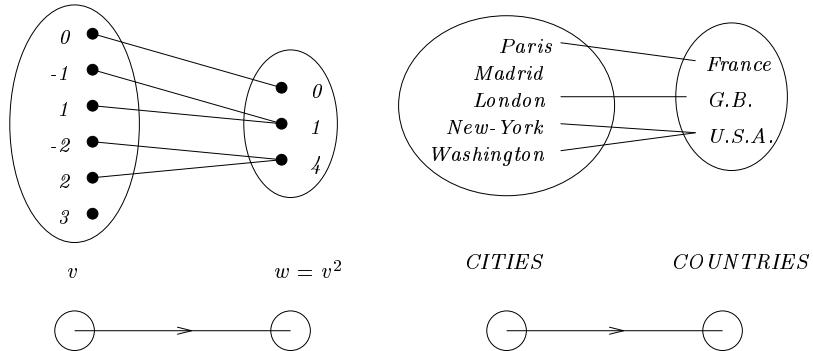

Figure 2: Two examples of functional constraints

2.1 Functional Constraints: Definition

We first define what we call *functional constraints* (Figure 2 presents two examples of such constraints), before discussing related work. We then recall some graph theory notions before characterizing a property necessary for the method we present in this paper.

Definition 2.2 Given two variables x_i and x_k , we denote $x_i \rightarrow x_k$ iff for all a_i in D_i , there is at most one a_k in D_k such that $(a_i, a_k) \in R_{ik}$. We then denote $a_k = f_{ik}(a_i)$ (or $a_k = f_{i \rightarrow k}(a_i)$) if this value exists, ε otherwise.

A constraint C_{ik} is functional iff $x_i \rightarrow x_k$ or $x_k \rightarrow x_i$. In the following, we will call x_i the origin and x_k the target of the functional constraint $x_i \rightarrow x_k$.

From this definition, we can deduce a partition of the constraint set of the CSP: on the one hand C_f , the set of the functional constraints, on the other hand C_o , the others (the non functional constraints). A CSP is said to be functional if it contains *some* functional constraints ($C_f \neq \emptyset$), and *strictly functional* if it *only* contains such constraints: $C = C_f$ ($C_o = \emptyset$).

2.2 Related Work

In the field of constraint satisfaction problems, one of the most important objectives is to reduce computation time. Many studies have been carried out to achieve this (see for instance the references in the introduction of this paper). They permit to reduce, sometimes drastically, the time required to solve CSPs. However, an obstacle limits their efficiency: they are general methods, and, as such, they do not take into account the specificities of the problems to be solved, notably w.r.t. *semantics* of the constraints. This deficiency was overcome by various (and, for most of them, recent) results. They exhibit some classes of constraints which possess particular properties. These results fall into two classes: on the one hand, those proposing algorithms specifically adapted to some classes of constraints, more efficient than general algorithms, and on the other hand, those characterizing classes of “tractable” problems. In this section as in the rest of this paper, we will suppose that, unless otherwise stated, the networks are binary.

The first class contains those techniques which make use of the *semantics* of the constraints to propose specific processings, namely arc consistency filterings.

- Mohr and Masini (1988) propose to modify AC-4 to improve its efficiency on *equality*, *inequality* and *disequality* constraints. They reduce time complexity of AC-4 from $O(ed^2)$ in general case, to $O(ed)$ for those specific constraints.
- AC-5, a new arc-consistency algorithm, is presented by Van Hentenryck *et al.* (1992). Actually, AC-5 is not an algorithm: it should rather be considered as a model with several possible specializations, according to the classes of constraints to process (*e.g.*, *functional*¹, *anti-functional* and *monotonic* constraints — notice that these constraints respectively correspond to Mohr and Masini's *equality*, *disequality* and *inequality* constraints). AC-5 achieves arc-consistency in $O(ed)$ for those constraints, which is consistent with the former result.²

The second class contains those techniques which identify constraints for which some local consistency is sufficient to guarantee global consistency, or propose polynomial algorithms to solve some classes of problems.

- van Beek (1992) shows that path consistency induces global consistency if the constraints are *row convex*.³
- van Beek and Dechter (1994) show that if the constraints are *m-tight*⁴, then strong $(m + 2)$ -consistency induces global consistency.⁵
- A tractable class of binary constraints is identified by Cooper *et al.* (1994), 0/1/all constraints. If for any pair of variables x_i, x_j , every value of D_i is supported by either 0, 1 or *all* values of D_j , then there exists an algorithm, called ZOA (Zero/One/All), which either finds a solution, or informs that no solution exists in polynomial time (namely $O(ed(n + d))$). It is also shown that any other class of constraints closed under permutation and restriction of the domains is NP-complete.
- Kirousis (1993) presents a polynomial algorithm to solve CSPs with *implicational* constraints (which, for binary constraints, are the same as 0/1/all constraints⁶).

-
1. Which should in fact be called *bijective*.
 2. It is also shown that, in the field of constraint logic programming over finite domains, for a restricted class of basic constraints, node- and arc-consistency algorithms provide a decision procedure whose complexity is the same as the complexity of AC-5, namely $O(ed)$.
 3. A binary constraint c_{ij} is *row convex* iff for any $a_i \in D_i$, all its supports are consecutive in D_j , provided there exists an (implicit) ordering of the domains.
 4. A binary constraint c_{ij} is *m-tight* iff every value $a_i \in D_i$ is supported by either at most m values in D_j , or *all* values of D_j , and, conversely, every value $a_j \in D_j$ either has at most m supports in D_i or is supported by *all* values of D_i .
 5. They furthermore show how this result applies to non-binary networks: for any CSP whose constraints have arity r or less and are at most *m-tight* (an r -ary constraint is *m-tight* iff all its binary projections are *m-tight*), if the CSP is strongly $((m + 1)(r - 1) + 1)$ -consistent, then it is globally consistent.
 6. For the sake of simplicity we will not present non-binary implicational constraints (for which an $O(d^2 r^2 n e)$ algorithm is presented), nor a parallel algorithm, also studied in his paper.

A first comment about those results: a class of binary constraints is a subclass of all those presented above, namely *bijective* constraints: they are 1-tight, 0/1(/all), and row convex. Bijective constraints are known to be tractable. Notice that constraints called *functional* by van Beek (1992) and by Van Hentenryck *et al.* (1992) are actually *bijective* constraints⁷. On the other hand, a functional constraint $x_i \rightarrow x_j$ is neither necessarily 1-tight, nor 0/1/all (see for example constraint $w = v^2$ in Figure 2), but R_{ij} remains row convex (even though R_{ji} may not be). But achieving path consistency in a network whose constraints are all functional may create non functional constraints (or transform some functional constraint into non functional ones). van Beek's result does not apply anymore (since there are non row convex constraints). Functional constraints, unlike bijective constraints, are intractable in general case.

The second comment is more important: all of those results assume that *all* of the constraints of the network belong to a given class (*e.g.*, m -tight, 0/1/all, row convex...), and only apply in this case. The difference, and, in our opinion, an interesting improvement, is that the results we present in this paper also apply when only *some* of the constraints are functional.

In a previous paper (David, 1993), it is shown that in a path consistent CSP, any consistent instantiation can be extended to a solution if, for every non-instantiated variable, there exists a sequence of functional or bijective constraints from an (any) instantiated variable to this non-instantiated variable. A subset of the variables is thus defined, such that any of its consistent instantiation can be linearly extended to a solution. Actually, path consistency is not necessary: a weaker local consistency, *pivot consistency*, is sufficient, as we now propose to show.

2.3 Functional Constraints and Directed Graphs

If a CSP \mathcal{P} is functional, its constraint graph can be divided into two subsets. C_f contains the (directed) arcs representing the functional constraints, where an arc is directed from x_i to x_k iff $x_i \rightarrow x_k$, and C_o contains the edges (*i.e.*, undirected), for non functional constraints. We denote $\mathcal{G} = (X, C_f \cup C_o)$ this graph, and $\mathcal{G}_f = (X, C_f)$ its directed subgraph.

Before going further, we need to recall some graph theory notions: the *descendant* of a vertex (variable), and the *root* of a directed graph:

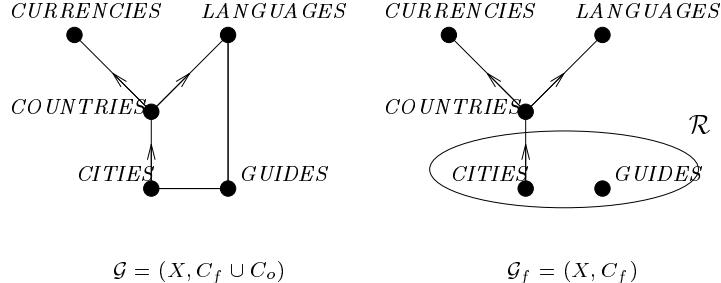

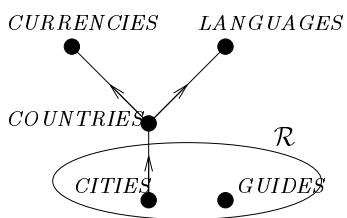

Definition 2.3 (Berge, 1970) *A vertex x_k is a descendant of x_i in a directed graph (X, C_f) iff there exists in C_f a path $(x_i, x_{j_1}, \dots, x_{j_q}, \dots, x_{j_p}, x_k)$ such that $x_i \rightarrow x_{j_1}, \dots, x_{j_q} \rightarrow x_{j_{q+1}}, \dots, x_{j_p} \rightarrow x_k, \forall q \in 1..p - 1$.*

A vertex x_r is a root of a directed graph (X, C_f) iff any other vertex is a descendant from x_r .

By extension, we define a *root set* of a directed graph. It is easy to find out that a *root* is a root set which contains a single vertex.

Definition 2.4 *A subset \mathcal{R} of X is a root set of a directed graph (X, C_f) iff any vertex of $X - \mathcal{R}$ is a descendant from an element of \mathcal{R} . \mathcal{R} is called minimal iff there does not exist a root set \mathcal{R}' such that $\mathcal{R}' \subset \mathcal{R}$. \mathcal{R} is called minimum iff there does not exist a root set \mathcal{R}' such that $|\mathcal{R}'| < |\mathcal{R}|$.*

7. A constraint c_{ij} is bijective iff it is functional from x_i to x_j ($x_i \rightarrow x_j$) and from x_j to x_i ($x_j \rightarrow x_i$).

Figure 3: Subgraph and root set of \mathcal{P}_{ex} 

GUIDES, CITIES, COUNTRIES, CURRENCIES, LANGUAGES or *CITIES, GUIDES, COUNTRIES, LANGUAGES, CURRENCIES* are both \mathcal{R} -compatible.

GUIDES, CITIES, LANGUAGES, COUNTRIES, CURRENCIES is prefixed by \mathcal{R} , but it is not \mathcal{R} -compatible: *LANGUAGES* has no ancestor x_i in this ordering such that $x_i \rightarrow LANGUAGES$.

GUIDES, LANGUAGES, COUNTRIES, CURRENCIES, CITIES is not \mathcal{R} -compatible: it is not prefixed by \mathcal{R} .

Figure 4: \mathcal{R} -compatible and non \mathcal{R} -compatible orderings of \mathcal{P}_{ex}

Figure 3 illustrates the notions of directed subgraph and of root set (here, a *minimum* root set) applied to our example \mathcal{P}_{ex} . Notice that the arc is only directed from *COUNTRIES* to *CURRENCIES*, and not from *CURRENCIES* to *COUNTRIES* though we have both *COUNTRIES* \rightarrow *CURRENCIES* and *CURRENCIES* \rightarrow *COUNTRIES*. This is only for the sake of simplicity: this information will not be useful in the following.

With a root set \mathcal{R} , we associate *\mathcal{R} -compatibility*, a property that can be verified by an ordering of X :

Definition 2.5 An ordering of X x_1, x_2, \dots, x_n is called \mathcal{R} -compatible iff:

1. $\forall i \leq |\mathcal{R}|$, $x_i \in \mathcal{R}$, and
2. $\forall k > |\mathcal{R}|$, $\exists j < k$ such that $x_j \rightarrow x_k$.

In other words, the first variables in this ordering are those which belong to \mathcal{R} (we then say that this ordering is *prefixed* by \mathcal{R}), and any other variable x_k has at least one ancestor x_j in the ordering (x_j is ordered before x_k) such that $x_j \rightarrow x_k$ (see Figure 4).

3. Pivot Consistency

First of all, why did we call it *pivot consistency*? Pivot consistency depends on the assignment ordering⁸. On every step of the assignment, two elements have to be distinguished: firstly, the set of the formerly instantiated variables (the *instantiated set*), and secondly the

8. Similarly to directional path consistency and adaptative consistency (Dechter & Pearl, 1988).

next variable to be instantiated. One can consider pivot consistency as a property between each instantiated set and the next variable to be instantiated. For each of these sets, a constraint has a particular role to play: the consistency checks turn on it. This constraint is thus called the *pivot* of the set.

3.1 Presentation

Further in this section, we will introduce the definition of pivot consistency in 3 steps: consistency between 3 variables, then pivot of a subset of X , and finally pivot consistency of the CSP.

Definition 3.1 Let $x_i, x_j, x_k \in X$ such that $C_{ik}, C_{jk} \in C$. C_{ik} and C_{jk} are x_k -compatible iff any tuple of R_{ij} has at least one support in D_k for C_{ik} and C_{jk} . Formally, $\forall (a_i, a_j) \in R_{ij}, \exists a_k \in D_k$ s.t. $(a_i, a_k) \in R_{ik}$ and $(a_j, a_k) \in R_{jk}$

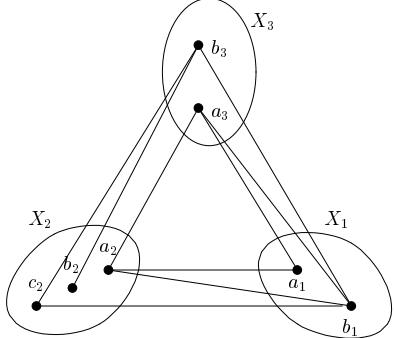

Four comments arise from this definition:

1. The existence of a constraint between x_i and x_j is not compulsory: the relation R_{ij} may be universal.
2. C_{ik} and C_{jk} are not necessarily different. If not, C_{ik} must be x_k -compatible with itself; in that case we assimilate the pair (a_i, a_i) of the relation R_{ii} to the value a_i of the domain D_i .
3. This definition may be seen as a local version of strong 3-consistency (2 and 3 consistencies):
 - 2-consistency: it is due to the remark above: any value in D_i must have a support in D_k .
 - 3-consistency: any consistent instantiation of $\{x_i, x_j\}$ may be extended to a third variable, here x_k .
4. Knowing that path consistency is equivalent to 3-consistency, we can deduce that path consistency can be rewritten in terms of x_k -compatibility:
A CSP is path consistent iff for all x_i, x_j, x_k pairwise distinct, $\{x_i, x_k\}$ and $\{x_j, x_k\}$ are both x_k -compatible.

We already said that some constraints called the *pivots* have a particular part to play; we now define them:

Definition 3.2 Let $Y \subset X$ and $C_{ik} \in C$ s.t. $x_i \rightarrow x_k$, $x_k \in X - Y$ and $x_i \in Y$. $x_i \rightarrow x_k$ is a pivot of Y iff $\forall x_j \in Y$ s.t. $C_{jk} \in C$, C_{ik} and C_{jk} are x_k -compatible.

In other words, given any proper subset Y of X , a functional constraint $x_i \rightarrow x_k$ “coming out” from Y ($x_i \in Y$ and $x_k \in X - Y$) is a pivot of Y if and only if for any consistent instantiation (a_i, a_j) of x_i and of any other variable x_j in Y , there exists at least one value a_k in D_k such that (a_i, a_j) can be extended to a consistent instantiation (a_i, a_j, a_k) of $\{x_i, x_j, x_k\}$. As for functional constraints, we call x_i the *origin* and x_k the *target* of the pivot $x_i \rightarrow x_k$.

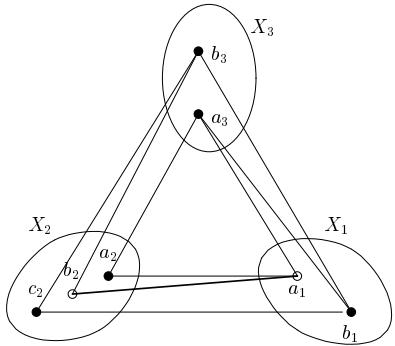

$\mathcal{R} = \{x_1, x_2\}$
The pivot of $\{x_1, x_2\}$ is $x_2 \rightarrow x_3$

This CSP is pivot consistent: the 3 pairs of R_{12} , that is (a_1, a_2) , (b_1, a_2) and (b_1, c_2) all have a support in D_3 (respectively a_3 , a_3 and b_3).

On the other hand, it is neither path consistent, since (b_2, b_3) has no support in D_1 , nor arc consistent, since b_2 has no support in D_1 .

Figure 5: A pivot consistent CSP

$\mathcal{R} = \{x_1, x_2\}$
The pivot candidate of $\{x_1, x_2\}$ is $x_2 \rightarrow x_3$.

This CSP is not pivot consistent: (a_1, b_2) has no support in D_3 .

Figure 6: A non pivot consistent CSP

Now that the pivot of a subset Y of X has been defined, we can introduce the notion of *pivot consistency* of a CSP:

Definition 3.3 Given a CSP $\mathcal{P} = (X, D, C, R)$, a root set \mathcal{R} of (X, C) and an \mathcal{R} -compatible assignment ordering x_1, x_2, \dots, x_n , we say \mathcal{P} is pivot consistent w.r.t. this ordering iff $\forall k > r = |\mathcal{R}|, \exists h < k$ s.t. $x_h \rightarrow x_k$ is a pivot of $Y_{k-1} = X_1, X_2, \dots, X_{k-1}$.

Informally, every variable which does not belong to \mathcal{R} is the target of a pivot whose origin is before it in the assignment ordering. Figures 5 and 6 show a pivot consistent CSP and a non pivot consistent CSP.

Pivot consistency of a CSP relies on the existence of a set of functional constraints possessing particular properties: the pivots (Definition 3.3 above). Thus, a *minimum* set of functional constraints can be characterized, so that the CSP is pivot consistent. This is the purpose of the three conditions stated in Definition 3.4:

- condition 1 ensures there exists a pivot for each Y_{k-1} , $k > r$: the network is therefore pivot consistent;
- conditions 2 and 3 leave unnecessary constraints out: only one pivot needs to “target” each $x_k \in X - \mathcal{R}$, and no pivot is required inside \mathcal{R} .

Definition 3.4 Given a CSP $\mathcal{P} = (X, D, C = C_f \cup C_o, R)$, a root set \mathcal{R} , an \mathcal{R} -compatible assignment ordering x_1, x_2, \dots, x_n , and a set of functional constraints $P \subseteq C_f$, if the following three conditions are satisfied

1. $\forall x_k \in X - \mathcal{R}, \exists x_h \rightarrow x_k \in P$ s.t. $h < k$ and $x_h \rightarrow x_k$ is pivot of Y_{k-1}
(any variable of $X - \mathcal{R}$ is the target of a pivot)
2. $\forall x_k \in X - \mathcal{R}, \{x_h \rightarrow x_k \in P \text{ and } x_j \rightarrow x_k \in P\} \Rightarrow h = j$
(any variable of $X - \mathcal{R}$ is the target of at most one pivot)
3. $\forall x_j \in \mathcal{R}, \nexists x_i \rightarrow x_j \in P$
(no variable of \mathcal{R} is the target of a pivot)

then P is called a pivot set of the CSP, and \mathcal{P} is pivot consistent.

We have introduced a new local consistency, pivot consistency. However, as for any local consistency, a CSP generally does not satisfy it. The problem has then to be *filtered* in order to obtain its *pivot consistent closure*, which is presented in the next section. This filtering is achieved w.r.t. a given pivot set P : this is why we now propose the definition of pivot consistency *with respect to a pivot set P* :

Definition 3.5 Given a CSP $\mathcal{P} = (X, D, C, R)$, a root set \mathcal{R} of (X, C) , an \mathcal{R} -compatible assignment ordering x_1, x_2, \dots, x_n and a constraint set $P \subseteq C$, we say \mathcal{P} is pivot consistent with respect to P and this ordering iff P is a pivot set of \mathcal{P} .

3.2 Pivot Consistent Closure

Let us assume a CSP \mathcal{P} is not pivot consistent, and that we wish to make it so. We then obtain a new problem, say \mathcal{P}^p , but we want this problem to meet some properties. The purpose of this section is to specify these properties. We first define the *pivot consistent closure* of a given CSP:

Definition 3.6 $\mathcal{P}^p = (X, D^p, C^p, R^p)$ is called the pivot consistent closure of the CSP $\mathcal{P} = (X, D, C, R)$ iff

1. $\mathcal{P}^p \trianglelefteq \mathcal{P}$ (i.e., $\forall i \in 1..n, D_i^p \subseteq D_i$, $C \subseteq C^p$, and $\forall i, j \in 1..n, R_{ij}^p \subseteq R_{ij}$ or $C_{ij} \notin C$), and
2. \mathcal{P}^p is pivot consistent, and
3. \mathcal{P}^p is maximal: there does not exist \mathcal{P}' pivot consistent such that $\mathcal{P}^p \trianglelefteq \mathcal{P}' \trianglelefteq \mathcal{P}$ and $\mathcal{P}^p \neq \mathcal{P}'$.

Before presenting two properties of the pivot consistent closure \mathcal{P}^p of a CSP \mathcal{P} , we introduce the following lemma, which we will use later in one of the proofs.

Lemma 3.1 Let $\mathcal{P} = (X, D, C, R)$ be a CSP. Let two CSPs $\mathcal{P}^1 = (X, D^1, C^1, R^1) \trianglelefteq \mathcal{P}$ and $\mathcal{P}^2 = (X, D^2, C^2, R^2) \trianglelefteq \mathcal{P}$ be pivot consistent w.r.t. a root set \mathcal{R} , a pivot set $P = \{x_{\text{Origin}(k)} \rightarrow x_k, \forall k > |\mathcal{R}|\}$ and an \mathcal{R} -compatible assignment ordering. Let the CSP $\mathcal{P}^3 = (X, D^3 = D^1 \sqcup D^2, C^3 = C^1 \cap C^2, R^3 = R^1 \sqcup R^2)$, with $D^3 = D^1 \sqcup D^2 = \{D_i^3 = D_i^1 \cup D_i^2 \forall i \in 1..n\}$ and $R^3 = R^1 \sqcup R^2 = \{R_{ij}^3 = R_{ij}^1 \cup R_{ij}^2 \forall i, j \in 1..n \text{ s.t. } C_{ij}^3 \in C^3\}$. Then firstly \mathcal{P}^3 is pivot consistent w.r.t. these same sets \mathcal{R} and P and this same \mathcal{R} -compatible assignment ordering, and secondly $\mathcal{P}^1, \mathcal{P}^2 \trianglelefteq \mathcal{P}^3 \trianglelefteq \mathcal{P}$.

Proof: We first show that \mathcal{P}^3 is pivot consistent. Let us denote $x_{Origin(k)} \rightarrow x_k$ (or, more briefly, $x_{O(k) \rightarrow X_k}$) the pivot whose target is x_k in \mathcal{P}^1 and \mathcal{P}^2 , for all $k > |\mathcal{R}|$. Let us show that for all $k > |\mathcal{R}|$, $x_{O(k) \rightarrow X_k}$ is the pivot of Y_{k-1} in \mathcal{P}^3 . Let x_j in Y_{k-1} such that $c_{jk} \in C^1 \cap C^2$. For all $(a_j, a_{O(k)}) \in R_{jO(k)}^3$, either $(a_j, a_{O(k)}) \in R_{jO(k)}^1$ or $(a_j, a_{O(k)}) \in R_{jO(k)}^2$. If $(a_j, a_{O(k)}) \in R_{jO(k)}^1$: as \mathcal{P}^1 is pivot consistent, there exists a_k in D_k^1 such that $(a_j, a_k) \in R_{jk}^1$ (therefore R_{jk}^3) and $(a_{O(k)}, a_k) \in R_{O(k)k}^1$ (therefore $R_{O(k)k}^3$). It is the same if $(a_j, a_{O(k)}) \in R_{jO(k)}^2$. c_{jk} and $x_{O(k)} \rightarrow x_k$ are consequently x_k -compatible: $x_{O(k)} \rightarrow x_k$ is pivot of Y_{k-1} in \mathcal{P}^3 .

For all $k > |\mathcal{R}|$, there exists $x_{O(k)} \rightarrow x_k$ pivot of Y_{k-1} : \mathcal{P}^3 is pivot consistent.

Let us now show that $\mathcal{P}^1, \mathcal{P}^2 \trianglelefteq \mathcal{P}^3 \trianglelefteq \mathcal{P}$:

$$\bullet \forall i \in 1..n, D_i^3 = D_i^1 \cup D_i^2, \text{ so } D_i^1 \subseteq D_i^3 \text{ and } D_i^2 \subseteq D_i^3. \quad (1)$$

$$\text{Furthermore, we have } D_i^1 \subseteq D_i \text{ and } D_i^2 \subseteq D_i; \text{ consequently, } D_i^3 \subseteq D_i. \quad (1')$$

$$\bullet C^3 = C^1 \cap C^2, \text{ so } C^3 \subseteq C^1 \text{ and } C^3 \subseteq C^2. \quad (2)$$

$$\text{Also, since } C \subseteq C^1 \text{ and } C \subseteq C^2, \text{ we have } C \subseteq C^3 = C^1 \cap C^2. \quad (2')$$

$$\bullet \forall i, j \in 1..n \text{ such that } c_{ij}^3 \in C^3, R_{ij}^3 = R_{ij}^1 \cup R_{ij}^2 \text{ so } R_{ij}^1 \subseteq R_{ij}^3 \text{ and } R_{ij}^2 \subseteq R_{ij}^3. \quad (3)$$

$$\bullet \forall i, j \in 1..n \text{ such that } c_{ij} \in C, \text{ do we have } R_{ij}^3 \subseteq R_{ij} ? \text{ Let } c_{ij} \in C. \text{ Then } c_{ij}^3 \in C^3 \\ (C \subseteq C^3). \text{ By construction of } R^3, \text{ we therefore have } R_{ij}^3 = R_{ij}^1 \cup R_{ij}^2. \text{ Now } R_{ij}^1 \subseteq R_{ij} \text{ and } R_{ij}^2 \subseteq R_{ij}, \text{ which implies } R_{ij}^3 \subseteq R_{ij}. \quad (3')$$

We deduce from (1), (2) and (3) that $\mathcal{P}^1 \trianglelefteq \mathcal{P}^3$ and $\mathcal{P}^2 \trianglelefteq \mathcal{P}^3$, and $\mathcal{P}^3 \trianglelefteq \mathcal{P}$ from (1'), (2') and (3'). \square

We can now present the properties we announced in the beginning of this section.

Property 3.2 *There only exists one maximal $\mathcal{P}^p \trianglelefteq \mathcal{P}$ pivot consistent, for a given root set \mathcal{R} , a given pivot set and a given assignment ordering.*

Proof: Suppose that \mathcal{P}^p is not unique: thus, there exists $\mathcal{P}' = (X, D', C', R') \trianglelefteq \mathcal{P}$ such that \mathcal{P}' is maximal and pivot consistent, and $\mathcal{P}' \neq \mathcal{P}^p$. Let us build the CSP $\mathcal{P}'' = (X, D' \sqcup D', C' \cap C', R' \sqcup R')$. This CSP is pivot consistent and $\mathcal{P}^p \trianglelefteq \mathcal{P}'' \trianglelefteq \mathcal{P}$ (Lemma 3.1): \mathcal{P}^p is not maximal, which contradicts the previous assumption. \square

The second property of \mathcal{P}^p is perhaps the most important:

Property 3.3 *Both CSPs \mathcal{P} and \mathcal{P}^p are equivalent, in that they have the same set of solutions.*

Proof: Let us denote $\mathcal{S}(\mathcal{P})$ and $\mathcal{S}(\mathcal{P}^p)$ their respective sets of solutions. Obviously, $\mathcal{S}(\mathcal{P}^p) \subseteq \mathcal{S}(\mathcal{P})$. Let us now show that $\mathcal{S}(\mathcal{P}) \subseteq \mathcal{S}(\mathcal{P}^p)$: suppose there exists $I_n = (s_1, \dots, s_n)$ solution of \mathcal{P} which is not a solution of \mathcal{P}^p . Then $\exists i, j \in 1..n$ such that $(s_i, s_j) \notin R_{ij}^p$. Now $(s_i, s_j) \in R_{ij}$ (I_n is a solution of \mathcal{P}): as \mathcal{P}^p is maximal, that means that (s_i, s_j) has no support for at least one constraint: $\exists k$ s.t. $\forall a_k \in D_k, (s_i, a_k) \notin R_{ik}$ or $(s_j, a_k) \notin R_{jk}$. We therefore have $(s_i, s_k) \notin R_{ik}$ or $(s_j, s_k) \notin R_{jk}$: I_n is not a solution of \mathcal{P} , that is $\mathcal{S}(\mathcal{P}) \subseteq \mathcal{S}(\mathcal{P}^p)$. \square

We now know that there exists a unique CSP \mathcal{P}' , called the *pivot consistent closure* of \mathcal{P} , such that $\mathcal{P}' \trianglelefteq \mathcal{P}$, \mathcal{P}' is maximal and \mathcal{P}' is pivot consistent. Moreover, this CSP has the same set of solutions as \mathcal{P} , the problem it comes from. But, even though it is interesting to know that such a CSP exists, it seems reasonable to wish to obtain it: that is the purpose of the next section, which proposes an algorithm achieving a pivot consistent filtering.

3.3 A Filtering Algorithm

First, a notation: the set of the functional constraints $x_h \rightarrow x_k$ chosen to be the pivots of each Y_k is called a *set of pivot candidates*, and denoted PC . After the filtering, $PC = P$, the pivot set. We will suppose in the course of this section that both the assignment ordering and PC are known; we explain how they are obtained in appendix A.2.

The algorithm is composed of several procedures. Their different levels represent the three steps followed to define pivot consistency. We present these procedures in an ascending way:

1. Make the constraints C_{jk} and $C_{hk} = x_h \rightarrow x_k$ x_k -compatible.
2. Compute a pivot $x_h \rightarrow x_k$ for all x_k in $X - \mathcal{R}$
3. Achieve pivot consistency for the CSP.

Procedure **Compatible** (x_h, x_k, x_j) makes constraints $x_h \rightarrow x_k$ and C_{jk} x_k -compatible: it removes from R_{hj} those tuples which do not have a common support in D_k for these two constraints. If necessary, it creates the constraint C_{hj} between the variables x_h and x_j .

```

Procedure Compatible( $x_h, x_k, x_j$ )
begin
    for all  $(a_h, a_j) \in R_{hj}$  do
         $a_k \leftarrow f_{hk}(a_h)$ 9
        if  $(a_h, a_k) \notin R_{hk}$  or  $(a_j, a_k) \notin R_{jk}$  then Suppress  $(a_h, a_j)$  from  $R_{hj}$ 
    end for
end

```

Procedure **Pivot** (x_h, x_k) makes all constraints C_{jk} containing x_k and such that $x_j \in Y_{k-1}$ x_k -compatible with $x_h \rightarrow x_k$ by successive calls to the subroutine **Compatible** (x_h, x_k, x_j). After its computation, $x_h \rightarrow x_k$ is therefore a pivot of Y_{k-1} .

```

Procedure Pivot( $x_h, x_k$ )
begin
    for all  $x_j \in Y_{k-1}$  s.t.  $C_{jk} \in C$  do Compatible( $x_h, x_k, x_j$ )
end

```

The CSP is pivot consistent iff any variable x_k of $X - \mathcal{R}$ is the target of a pivot of Y_{k-1} .

9. By convention, if a_h has no support in D_k for C_{hk} , we denote $f_{hk}(a_h) = \varepsilon$, and, of course $(a_h, \varepsilon) \notin R_{hk}$ and $(a_j, \varepsilon) \notin R_{jk}$.

```

Pivot consistent filtering
begin
  for  $k \leftarrow n$  to  $r + 1$  do
     $x_h \leftarrow$  Origin of the pivot candidate whose target is  $x_k$ 
    Pivot( $x_h, x_k$ )
  end for
end

```

Proposition *This algorithm achieves pivot consistency (the resulting problem is the pivot consistent closure of \mathcal{P} w.r.t. the chosen data).*

Proof: We clearly see that after computing $\text{Pivot}(x_h, x_k)$, $x_h \rightarrow x_k$ is a pivot of Y_{k-1} . Moreover, only the necessary suppressions are performed: according to the definition of **Compatible**, a pair is suppressed from a relation only if it has no support in the target of the current pivot candidate.

We consequently simply have to show that any suppression due to $\text{Pivot}(x_h, x_k)$ has no influence on the pivots $x_g \rightarrow x_l$ for $l > k$. More precisely, if $x_g \rightarrow x_l$ is a pivot of Y_{l-1} before computing $\text{Pivot}(x_h, x_k)$, then it will remain so.

For the sake of brevity, we will denote in the course of this proof $Pv(k)$ the computation of the procedure $\text{Pivot}(x_h, x_k)$. Let l be such that $x_g \rightarrow x_l$ is a pivot of Y_{l-1} before $Pv(k)$. Suppose $x_g \rightarrow x_l$ is no longer a pivot of Y_{l-1} after $Pv(k)$. Consequently, there exists $j < l$ such that C_{jl} and C_{gl} are not x_l -compatible: $\exists (a_j, a_g) \in R_{jg}$ s.t. $(a_j, a_l) \notin R_{jl}$ or $(a_g, a_l) \notin R_{gl}$. $Pv(k)$ has thus suppressed (a_j, a_l) from R_{jl} or (a_g, a_l) from R_{gl} . This is impossible, since by definition procedure $\text{Pivot}(x_h, x_k)$ only modifies constraints C_{hi} , with $h, i < k$, so *a fortiori* $h, i < l$ ($k < l$). So, $Pv(k)$ does not influence pivots $x_g \rightarrow x_l$ for $l > k$. This algorithm therefore computes the pivot consistent closure of a CSP. \square

Notice that unlike arc or path consistencies which only need knowledge about the CSP, the pivot consistent closure is in addition defined w.r.t. a root set, a pivot set and an assignment ordering: Figure 7 shows how the choice of the pivot(s) may influence the filtered problem.

3.4 Application to the Example

In this section, we illustrate the filtering algorithm using the travel agency example. We first recall the initial problem and expose the data necessary to the algorithm (root set \mathcal{R} , set of pivot candidates PC and \mathcal{R} -compatible ordering).

$$\mathcal{R} = \{GUIDES, CITIES\}$$

$$PC = \{CITIES \rightarrow COUNTRIES, \\ COUNTRIES \rightarrow CURRENCIES, \\ COUNTRIES \rightarrow LANGUAGES\}$$

An \mathcal{R} -compatible ordering is:

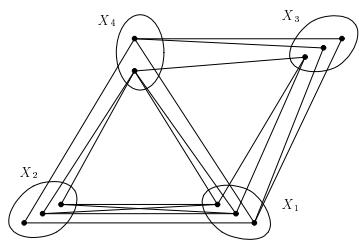

$$GUIDES, CITIES, COUNTRIES, CURRENCIES, LANGUAGES$$

In order to achieve pivot consistency, we need to compute $\text{Pivot}(COUNTRIES, LANGUAGES)$, $\text{Pivot}(COUNTRIES, CURRENCIES)$ and $\text{Pivot}(CITIES, COUNTRIES)$.

$$\mathcal{R} = \{x_1, x_2, x_3\}$$

The three possible pivots are $x_1 \rightarrow x_4$, $x_2 \rightarrow x_4$ and $x_3 \rightarrow x_4$.

The assignment ordering we have chosen is x_1, x_2, x_3, x_4 .

If we choose the pivot $x_1 \rightarrow x_4$ the filtering does not suppress anything; the resulting problem \mathcal{P}_1 is therefore the same as the initial one \mathcal{P} .

If we choose the pivot $x_2 \rightarrow x_4$ the filtering creates the constraint C_{23} , and does not change anything else; we obtain the problem \mathcal{P}_2 :

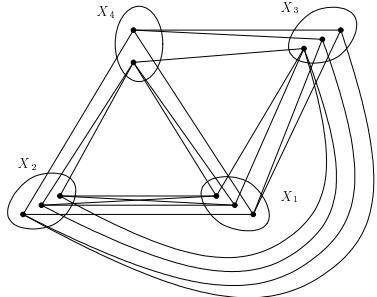

Figure 7: Pivot consistency: influence of the pivot

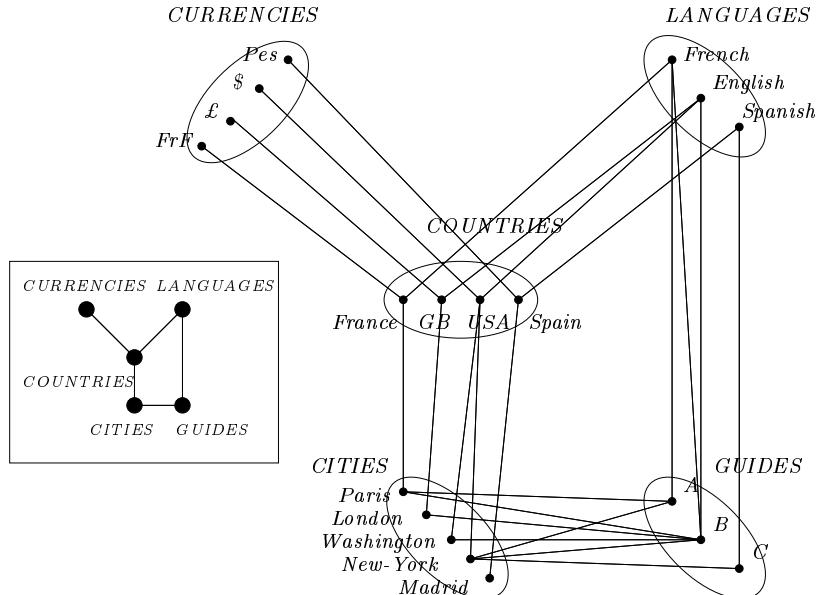

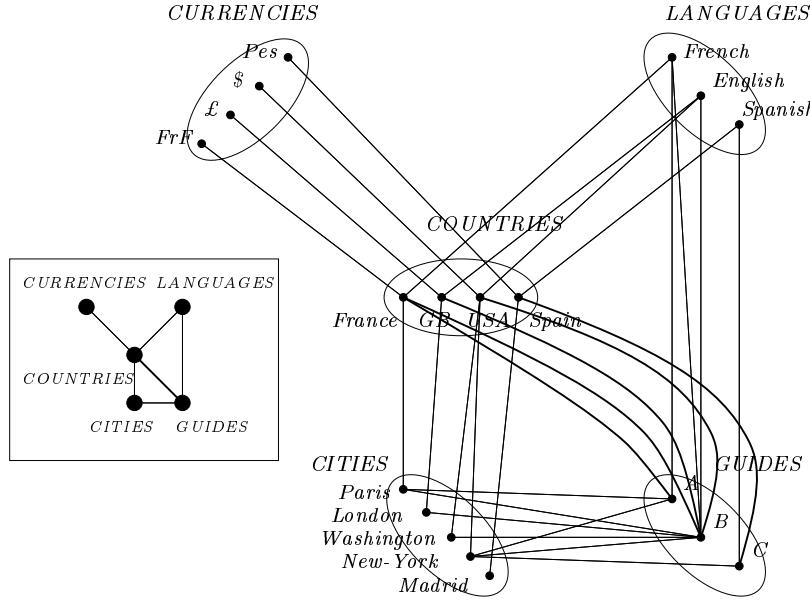

Figure 8: Constraint and consistency graphs of the initial \mathcal{P}_{ex}

Figure 9: After Pivot ($COUNTRIES, LANGUAGES$)

We now detail these computations:

- Computation of Pivot ($COUNTRIES, LANGUAGES$) (Figure 9):
We perform `Compatible` ($COUNTRIES, LANGUAGES, COUNTRIES$) which does not modify anything, and `Compatible` ($COUNTRIES, LANGUAGES, GUIDES$), which creates the constraint $\{GUIDES, COUNTRIES\}$.
- Computation of Pivot ($COUNTRIES, CURRENCIES$):
We perform `Compatible` ($COUNTRIES, CURRENCIES, COUNTRIES$) which does not modify anything.
- Computation of Pivot ($CITIES, COUNTRIES$) (Figure 10):
We perform `Compatible` ($CITIES, COUNTRIES, CITIES$) which does not change anything, and `Compatible` ($CITIES, COUNTRIES, GUIDES$), which modifies the constraint $\{GUIDES, CITIES\}$.

3.5 Pivot Consistency vs Path Consistency

We previously said that arc-and-path consistency was not necessary to give some properties to a functional CSP, and that pivot consistency was sufficient. We first show in this section that pivot consistency is a weakened form of path consistency, and in section 4 we will present some properties and a method for solving functional CSPs based upon them.

Note that, since pivot consistency is directed, one could wish to compare it not only with “full” path consistency, but also with *directional* path consistency. We therefore propose to present relationships between pivot consistency and both path consistency and directional path consistency. We will thus see that pivot consistency is a restricted version of directional path consistency as well.

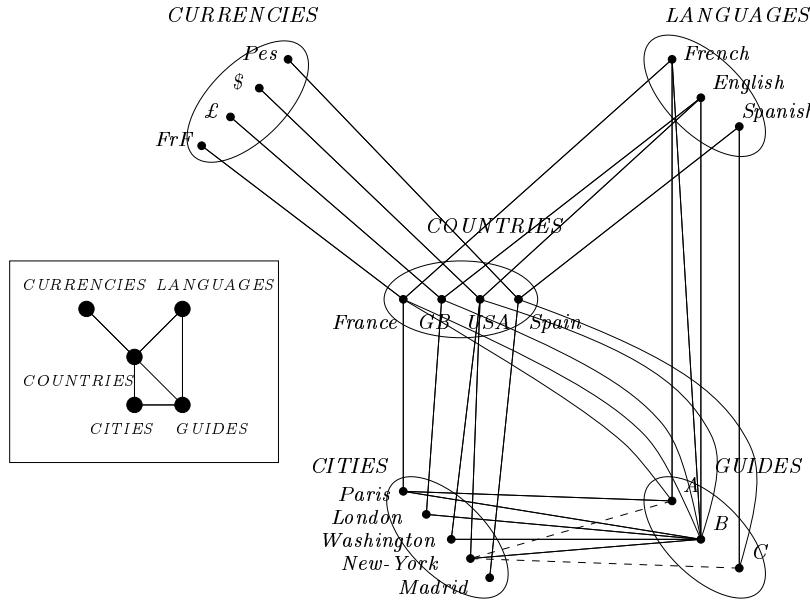

Figure 10: After Pivot ($CITIES, COUNTRIES$): end of the filtering

First, let us recall a remark we made when defining x_k -compatibility:

A CSP is path consistent iff for all x_k in X and for all x_h, x_i in X , $\{x_h, x_k\}$ and $\{x_i, x_k\}$ are x_k -compatible.

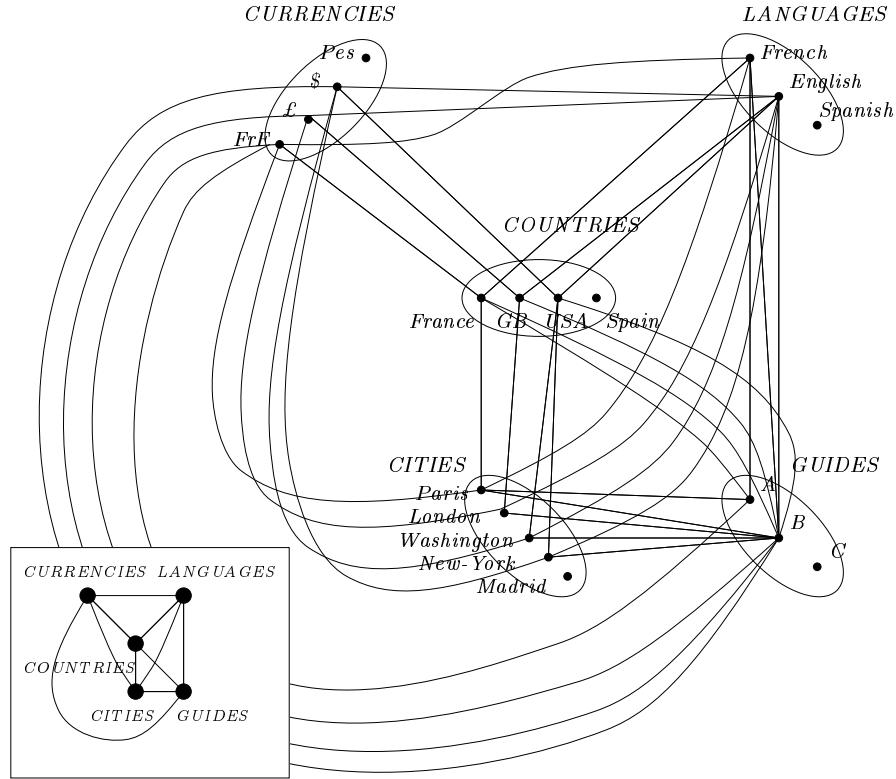

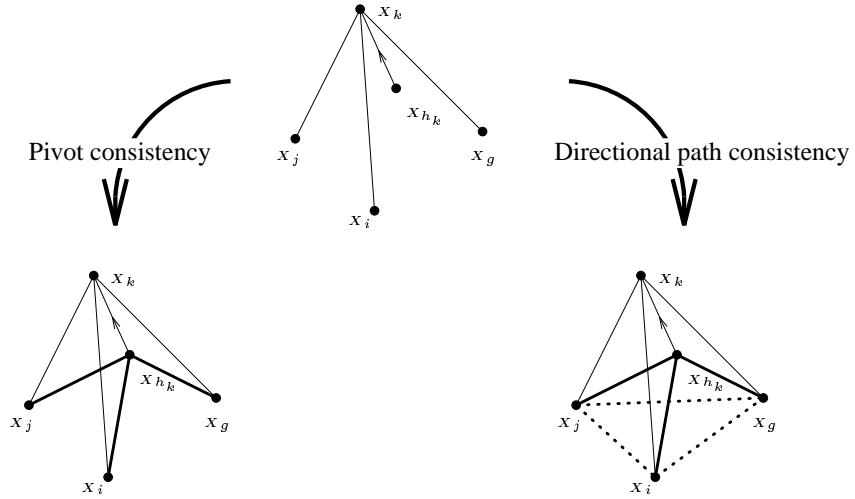

A slight difference appears with directional path consistency:

A CSP is directional path consistent iff for all x_k in X and for all x_h, x_i in X such that $h, i < k$, $\{x_h, x_k\}$ and $\{x_i, x_k\}$ are x_k -compatible.

Pivot consistency does not need so many requirements. First, x_k -compatibility is only required for variables in $X - \mathcal{R}$. Furthermore, for each of these x_k , not all of the possible pairs of constraints are filtered: as this consistency is directed, x_k -compatibility is only achieved for constraints whose first variable precedes x_k (the second one) in the assignment ordering. Finally, the filtering is only achieved w.r.t. the pivot candidate whose target is x_k (say $x_{h_k} \rightarrow x_k$). In other words,

A CSP is pivot consistent iff for all x_k in $X - \mathcal{R}$ and for all x_i in X such that $i < k$, $\{x_{h_k}, x_k\}$ and $\{x_i, x_k\}$ are x_k -compatible, provided that $x_{h_k} \rightarrow x_k \in PC$.

To sum up, one can roughly say that for each x_k , path consistency needs to consider $O(n^2)$ triangles, directional path consistency $O(k^2)$ and pivot consistency $O(k)$. The difference between path and pivot consistencies clearly appears on the travel agency example: only two constraints are altered. The first one ($\{GUIDES, COUNTRIES\}$) is created, and the second one ($\{GUIDES, CITIES\}$) is modified, whereas path consistency modified the five existing constraints, and created the five other possible constraints, making the constraint graph complete (see Figure 11). However, this example does not highlight any difference between pivot consistency and directional path consistency. Figure 12 presents how pivot consistency and directional path consistency may differently modify the constraint graph of a CSP when processing a node x_k .

Figure 11: Path consistent closure of \mathcal{P}_{ex} Figure 12: Processing pivot consistency and directional path consistency on node x_k , (with $g, h_k, i, j < k$): the bold edges represent the constraints possibly created by pivot consistency (w.r.t. $x_{h_k} \rightarrow x_k$), the dotted edges the extra ones possibly created by directional path consistency

Time complexity is lower for pivot consistency than for path consistency or directional path consistency, as will now be shown.

3.6 Complexity

Procedure **Pivot** is computed exactly once for each variable x_k in $X - \mathcal{R}$; it then calls at most $k - 1$ times procedure **Compatible** (once for each of the $k - 1$ former variables). Achieving x_k -compatibility between two constraints $c_{h,k}$ and $c_{i,k}$ corresponds to achieving path consistency for relation R_{hi} w.r.t. variable x_k . This operation needs $O(d^3)$ in general. But since the constraint $c_{h,k}$ is functional, this complexity is now $O(d^2)$. The overall complexity of the filtering is therefore

$$O\left(\sum_{k=r+1}^n (k-1)d^2\right) = O((n^2 - r^2)d^2)$$

(instead of $O(n^3d^3)$ for path consistency or directional path consistency¹⁰; n is the number of variables, d is the size of the domains and r is the size of the root set).

4. From a Local Instantiation to a Solution

The intrinsic characteristic of a local consistency is to ensure that a partial instantiation can be extended to a new variable. We first present the properties of pivot consistency, in particular the conditions under which a consistent partial instantiation may be extended to a solution. We then explain how to compute the data required by the filtering algorithm, and finally present a method for solving functional CSPs.

4.1 Properties

We proceed in two stages: first, the addition of a new variable to the current instantiation, then the extension from the root set to a solution.

Property 4.1 *Let $\mathcal{P} = (X, D, C, R)$ be a CSP, I_{k-1} be a consistent instantiation of Y_{k-1} , and x_k be a new variable to instantiate. If there exists $x_h \in Y_{k-1}$ such that $x_h \rightarrow x_k$ is a pivot of Y_{k-1} , then I_{k-1} may be extended into I_k , a consistent instantiation of Y_k .*

Proof: Let us show that any constraint included in Y_k is satisfied. Let $x_h \in Y_{k-1}$ such that $x_h \rightarrow x_k$ is a pivot of Y_{k-1} , and a_h its value in I_{k-1} . Consequently, there exists $a_k = f_{h \rightarrow k}(a_h)$. Let us denote $I_k = (a_1, \dots, a_h, \dots, a_{k-1}, a_k)$.

1. Any constraint satisfied by I_{k-1} and which does not contain x_k is therefore obviously also satisfied by I_k .
2. For all $i < k$ s.t. $c_{ik} \in C$. First, $x_i \in Y_{k-1}$: let a_i be its value in I_{k-1} . Second, $x_h \rightarrow x_k$ is a pivot of Y_{k-1} . c_{ik} and $x_h \rightarrow x_k$ are consequently x_k -compatible. We thus have $(a_i, a_k) \in R_{ik}$; so, c_{ik} is satisfied by I_k .

Every constraint included in Y_k is satisfied by I_k . Hence I_k is a consistent instantiation. \square

10. Note that achieving directional path consistency on functional CSPs is still $O(n^3d^3)$ and not $O(n^3d^2)$, since first functional constraints are not necessarily directed the right way (where a functional constraint is “properly” directed if its origin is before its target in the instantiation ordering), and second non functional constraints may be created by the processing.

We now present the theorem at the center of the method we introduce further.

Theorem 1 *Let $\mathcal{P} = (X, D, C, R)$, $\mathcal{R} \subseteq X$ a root set, and an \mathcal{R} -compatible assignment ordering such that \mathcal{P} is pivot consistent w.r.t. them. If a consistent instantiation of \mathcal{R} exists, then it can be extended to a backtrack-free solution.*

Proof: The variables of $X - \mathcal{R}$ only need to be instantiated along with the \mathcal{R} -compatible ordering: as each of them is the target of a pivot (since \mathcal{P} is pivot consistent), Property 4.1 is verified step by step from the instantiation of \mathcal{R} to a solution. \square

4.2 A Solving-by-Decomposing Method

In section 4.1 (Theorem 1), we saw that, given a consistent instantiation of \mathcal{R} , and provided that the problem is pivot consistent w.r.t. an \mathcal{R} -compatible assignment ordering and a pivot set, we can not only guarantee there is a solution to the whole problem, but also find it without any backtracking. We can therefore deduce a method from this property. We now introduce this method, decomposed into four phases, and for each of them, we present the time complexity and the result of its computation on the example.

Phase 1 Computation of a root set \mathcal{R} , a pivot candidate set PC and an \mathcal{R} -compatible assignment ordering.

This phase can roughly be outlined as finding the sources of a graph where each strongly connected component is reduced to one node (computation of \mathcal{R}), finding a set of directed arcs covering all nodes in $X - \mathcal{R}$ (PC) and then performing topological sort (assignment ordering). For more details, see appendices A.1 and A.2.

Complexity: $O(e + n)$ to compute \mathcal{R} (appendix A.1), and also $O(e + n)$ for PC and the assignment ordering (appendix A.2). So, for the whole phase: $O(e + n)$.

The root set is $\mathcal{R} = \{GUIDES, CITIES\}$.

The pivot candidate set is $PC = \{CITIES \rightarrow COUNTRIES, COUNTRIES \rightarrow CURRENCIES, COUNTRIES \rightarrow LANGUAGES\}$

The \mathcal{R} -compatible assignment ordering we chose is
 $GUIDES, CITIES, COUNTRIES, CURRENCIES, LANGUAGES$.

Phase 2 Pivot consistent filtering

Complexity: $O((n^2 - r^2)d^2)$ (see 3.6)

The pivot consistent problem is computed in section 3.4.

Phase 3 Instantiation of \mathcal{R}

Complexity: $O(e_{\mathcal{R}}d^r)$, where $e_{\mathcal{R}}$ is the number of constraints included in \mathcal{R} .

There are five consistent instantiations of $\mathcal{R} = \{GUIDES, CITIES\}$:

$\{(Alice, Paris), (Bob, Paris), (Bob, London), (Bob, Washington), (Bob, New-York)\}$

Phase 4 Instantiation of $X - \mathcal{R}$

Complexity: $O(n - r)$: extending a consistent instantiation of \mathcal{R} to a solution only needs linear time.

The solutions of the problem are:

$$\begin{aligned} & (Alice, Paris, France, FrF, French) \\ & (Bob, Paris, France, FrF, French) \\ & (Bob, London, GBob, £, English) \\ & (Bob, Washington, USA, \$, English) \\ & (Bob, New-York, USA, \$, English) \end{aligned}$$

The overall time complexity of this method is therefore $O((n^2 - r^2)d^2 + e_{\mathcal{R}}d^r)$. This method thus reduces the search for one solution (or all) of a functional CSP to the one induced by its root set \mathcal{R} . As the time required obviously depends on the size of \mathcal{R} , we immediately see how interesting it is to compute a minimum sized root set. A direct consequence is that the smaller \mathcal{R} is, the more efficient this method will be. It consequently seems worthwhile to know its size as soon as possible: this has been done in phase 1.

A last remark before concluding: the reader probably noticed that the number of consistent instantiations of \mathcal{R} is the same as the number of solutions of the whole problem. This is not a coincidence, as we see below:

Property 4.2 *Let \mathcal{P} be pivot consistent, and let \mathcal{R} be its root set. The number of solutions of \mathcal{P} equals the number of consistent instantiations of \mathcal{R} : each solution is the extension of exactly one of those instantiations.*

Proof: Let $I_r = (a_1, \dots, a_r)$ be a consistent instantiation of the root set $\mathcal{R} = \{x_1, \dots, x_r\}$. According to Theorem 1, I_r can be extended to at least one solution to \mathcal{P} . \mathcal{R} is a root set of \mathcal{G} . Any x_k in $X - \mathcal{R}$ is therefore a descendant from a variable x_{r_k} of \mathcal{R} . There consequently exists a unique value $a_k \in D_k$ such that $(a_{r_k}, a_k) \in R_{r_k k}$, and, so, an only consistent instantiation of $\mathcal{R} \cup x_k$ including I_r , therefore only one solution including I_r . Moreover, as two different instantiations of \mathcal{R} obviously cannot be extended to the same solution, there consequently exists a one to one mapping between the set of the consistent instantiations of \mathcal{R} and the set \mathcal{S} of the solutions to \mathcal{P} . \square

5. Conclusion

Taking into account semantic properties of the constraints is a still recent approach to increase the efficiency of finding solutions to CSPs. This paper belongs to this frame.

We first introduced a new local consistency, pivot consistency, to deal with functional constraints for a lower cost than path consistency (we furthermore showed that pivot consistency is a weak form of path consistency). We then proposed an algorithm to achieve pivot consistent filtering. Later, we studied some properties that pivot consistency provides a functional CSP with, in particular conditions under which a consistent instantiation can be extended to a solution.

We were then led to present a decomposition method based on those properties, which decreases the complexity of solving functional CSPs. An interesting point is that the search

for solutions to the former problem is reduced to the search for solutions to the subproblem induced by a particular subset, the root set; this new problem can be solved by any method, including heuristics.

Furthermore, we must add that this method deals with problems in which not all the constraints have to be functional (as we saw in the example). This is in our opinion an interesting improvement: most previous work dealing with properties of specific classes of constraints assumes that all the constraint of the network possess a given property, and only applies in this case.

However, some problems remain. First, and this is a classical problem as far as pre-processings are concerned: in what extent is the application of the method we present here useful? A partial answer can be given to this question: we indeed saw that one of the advantages of this method is that the cost of the search is known early in the process; one can thus estimate if the continuation of the process is worthwhile or not.

On the other hand, pivot consistency and the associated consistency properties can of course be generalized to non binary CSPs; yet, some problems appear: first of all, finding a minimum root set becomes exponential (it is the same problem as finding a *key* of minimum size in the field of relational databases, Lucchesi & Osborn, 1978); moreover, as we have seen, some constraints may be induced by the filtering processing; if this is not a problem for binary CSPs (the new constraints are still binary), in n -ary CSPs, some constraints may induce new ones of greater arity, which may from step to step lead to an explosion of the CSP arity.

Finding and characterizing classes of problems having root sets of small size as well as problems whose arity does not grow when achieving pivot consistency are therefore in the continuity of the work we presented in this paper.

To conclude, taking into account the semantics of constraints seems to be an interesting research area, and, as such, we can think of extending this kind of study (characterization of properties and of processings specific to a class of constraints) to other classes of constraints.

Appendix A. Computation of Structural Data

A.1 Computation of a Minimum Root Set \mathcal{R}

The example used in this paper is not suited to the illustration of the computation we present here; we therefore use another one (Figures 13 to 15).

Computation of \mathcal{G}_q , reduced graph of \mathcal{G}_f :

- 1: Compute $T = \{T_1, \dots, T_p\}$, the set of the strongly connected components of \mathcal{G}_f .
- 2: Compute graph $\mathcal{G}_q = (\mathcal{T}, C_q)$, where each vertex t_i of \mathcal{T} is the reduction of a strongly connected component T_i , and there exists an arc from t_i to t_j if and only if an arc existed from a vertex of T_i to a vertex of T_j .

Computation of the sources of \mathcal{G}_q , and the root set of \mathcal{G}_f :

- 3: Compute the set $S_q = \{t_{s_1}, \dots, t_{s_r}\}$ of the sources of \mathcal{G}_q .
- 4: Choose for each source t_{s_k} of S_q any vertex of T_{s_k} , which will represent it.
- 5: The set \mathcal{R} processed in that way is a root set of \mathcal{G}_f .

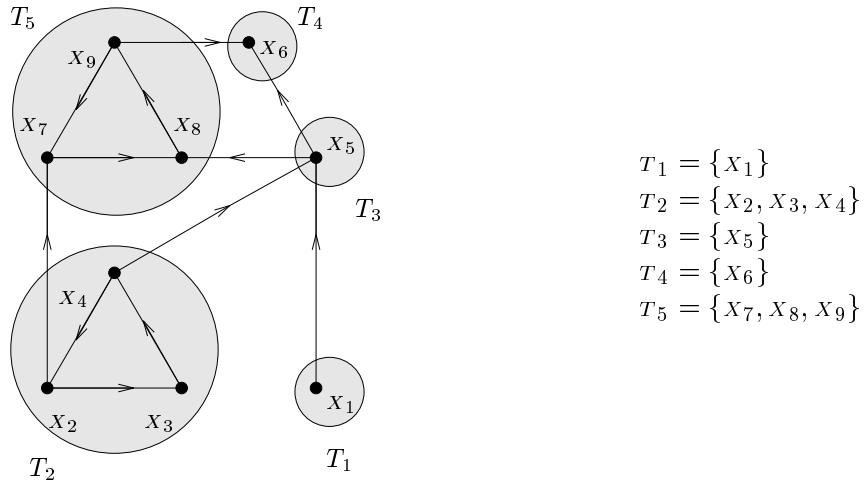

Figure 13: Step 1: the strongly connected components

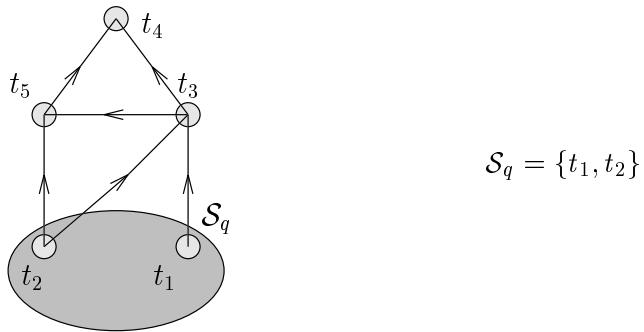

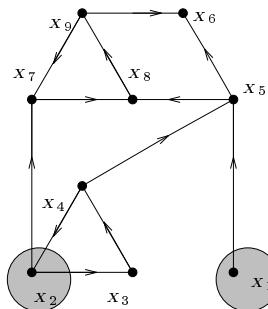

Figure 14: Steps 2 and 3: the reduced graph and its sources

The only possible vertex to represent t_1 is X_1 .

A vertex is chosen amongst $T_2 = \{X_2, X_3, X_4\}$ to represent t_2 , for instance X_2 .

We thus obtain $\mathcal{R} = \{X_1, X_2\}$

Figure 15: Steps 4 and 5: a minimum root set

A question arises: *Is the set \mathcal{R} really a minimum root set?*

There are actually two questions: first, is \mathcal{R} a root set? and if so, is this set *minimum*?

We first show that the set \mathcal{R} we computed is a root set:

Let us show that any vertex is a descendant from an element of \mathcal{R} . Let x_i be a vertex of $X - \mathcal{R}$. Two possibilities:

1. An element of \mathcal{R} belongs to the same strongly connected component as x_i . By definition, x_i is then a descendant from this element.
2. No element in \mathcal{R} belongs to the same strongly connected component as x_i . Let us denote T_i the strongly connected component which contains x_i , and t_i its reduction in the graph \mathcal{G}_q . So, t_i is not a source of this graph; consequently, there exists a source t_{s_i} in \mathcal{G}_q such that t_i is a descendant from t_{s_i} . Let x_{s_i} be the vertex of X we chose to represent t_{s_i} in \mathcal{R} . According to the definition of the reduced graph, knowing that t_i is a descendant from t_{s_i} , any element of T_i is a descendant from any element of T_{s_i} , and therefore from x_{s_i} . x_i is consequently a descendant from an element of \mathcal{R} .

\mathcal{R} is a root set. □

We now show that \mathcal{R} is *minimum* (*i.e.*, there does not exist any root set of smaller size): Let us denote $r = |\mathcal{R}|$. Assume there exists a root set \mathcal{R}' whose size is $r' < r$. Let $SCC(\mathcal{R}')$ be the set of the Strongly Connected Components that contain all the elements of \mathcal{R}' , and let $\mathcal{T}(\mathcal{R}')$ be the set of their reductions in \mathcal{G}_q . By definition of \mathcal{R} , the reduced graph \mathcal{G}_q has r sources. There exists at least one source t_{s_k} in \mathcal{G}_q which does not belong to $\mathcal{T}(\mathcal{R}')$ (since $|\mathcal{T}(\mathcal{R}')| \leq r' < r$). Consequently, there exists no path from an element of $\mathcal{T}(\mathcal{R}')$ to t_{s_k} . Let us denote $SCC(k)$ the strongly connected component reduced to t_{s_k} . From the definition of the reduced graph, there exists no path from an element of \mathcal{R}' to an element of $SCC(k)$. Consequently, \mathcal{R}' is not a root set.

\mathcal{R} is thus a *minimum* root set. □

Complexity: It is the same as the complexity required for computing the strongly connected components, that is $O(e + n)$ (Tarjan, 1972), if e is the number of edges and n the number of vertices.

A.2 Choice of the Pivots and Computation of an \mathcal{R} -compatible Order

We now describe how to choose the pivot candidates and to compute an \mathcal{R} -compatible ordering. We first present the conditions the pivot candidates must satisfy; we then present an algorithm that computes both PC and an \mathcal{R} -compatible ordering. The definition of pivot consistency implies two conditions on the pivots:

1. Any x_k in $X - \mathcal{R}$ must be the target of one and only one pivot, and no variable of \mathcal{R} is the target of a pivot.
2. If $x_h \rightarrow x_k$ is a pivot, then x_h is before x_k in the ordering.

For each x_k in $X - \mathcal{R}$, we have to choose a variable x_h in X so that $x_h \rightarrow x_k$ (x_h necessarily exists, since x_k does not belong to \mathcal{R}). Moreover, PC must not contain any circuit, which would be in contradiction with condition 2. A way to prevent circuits is to mark every

selected variable, and to select a new variable among the unmarked ones, which is the target of a functional constraint whose origin is already marked. This functional constraint is then included into PC , and its target (the new variable) is then marked. The set PC we obtain this way is the set of the pivot candidates used by the pivot consistency algorithm (section 3.3). This set induces a partial order $\prec_{\mathcal{R}}$ on X (we only have to add the transitivity constraints). In order to satisfy the conditions of Definition 3.3, the assignment ordering consequently has to be a linear extension of the partial order $\prec_{\mathcal{R}}$ prefixed by \mathcal{R} . Actually, computing $\prec_{\mathcal{R}}$ is not necessary: PC is sufficient to compute the linear extension. There are no conditions on the variables of \mathcal{R} ; the algorithm can thus be decomposed into two steps:

1. *Ordering of \mathcal{R}*

Number from 1 to $r = |\mathcal{R}|$ the variables of \mathcal{R} and mark them

2. *Ordering of $X - \mathcal{R}$*

Repeat

Choose a new unmarked variable x_k in $X - \mathcal{R}$ s.t. there exists a marked x_h s.t.

$x_h \rightarrow x_k$

Number and mark x_k

Until all variables are marked

Figure 16 presents an algorithm computing both the set of pivot candidates PC and an \mathcal{R} -compatible assignment ordering. Let us repeat that any linear extension issued from PC is an \mathcal{R} -compatible ordering.

- The set **Marked** contains the variables that have already been treated
- The set **NextPossible** contains the next variables that can be chosen, that is the unmarked ones which are the target of a functional constraint whose origin is marked
- The sets **Origin[j]** contain the origins of functional constraints whose targets are described above (**NextPossible**)
- **Num** represents the number of the current variable in the assignment ordering

Correctness:

- Set PC :

Condition 1: a functional constraint $x_h \rightarrow x_k$ is added to PC each time a new variable x_k is chosen: we therefore need to prove that any variable of $X - \mathcal{R}$ is selected *exactly* once, and that none is selected from \mathcal{R} . The variables are selected from **NextPossible**, which only contains unmarked variables; since no marked variable may be unmarked back, and every selected variable is marked, every variable can be selected at most once.

Let us now prove that every variable of $X - \mathcal{R}$ is *actually* (at least once) selected: at any time, **NextPossible** is the set of all direct descendants of the marked variables that do not belong to \mathcal{R} ; at each outer loop of step 2, a new variable is extracted from **NextPossible** and marked; from the definition of \mathcal{R} , all variables of $X - \mathcal{R}$ will therefore be reached and inserted in **NextPossible**.

```
begin
```

```
    Initializations
```

```
        Marked  $\leftarrow \emptyset$ 
        NextPossible  $\leftarrow \emptyset$ 
        for each  $i$  in  $1..n$  do Origin[ $i$ ]  $\leftarrow \emptyset$ 
        Num  $\leftarrow 1$ 
```

Step 1: Numbering of \mathcal{R}

```
    while Marked  $\neq \mathcal{R}$  do
        Choose  $x_i$  unMarked in  $\mathcal{R}$ 
        Mark  $x_i$  (* Add  $x_i$  to Marked *)
        Number  $x_i$  with Num
        Add 1 to Num
        for each  $x_i \rightarrow x_j$  s.t.  $x_j$  is unMarked and  $x_j \notin \mathcal{R}$  do
            Add  $x_j$  to NextPossible
            Add  $x_i$  to Origin[ $j$ ]
        end for
    end while
```

Step 2: Numbering of $X - \mathcal{R}$ — Construction of PC

```
    PC  $\leftarrow \emptyset$ 
    while Marked  $\neq X$  do
        Choose  $x_k$  in (and remove it from) NextPossible
        Mark  $x_k$  (* Add  $x_k$  to Marked *)
        Number  $x_k$  with Num
        Add 1 to Num
        Choose  $x_h$  in (and remove it from) Origin[ $k$ ]
        Add  $x_h \rightarrow x_k$  to PC
        for each  $x_k \rightarrow x_p$  s.t.  $x_p$  is unMarked do
            Add  $x_p$  to NextPossible
            Add  $x_k$  to Origin[ $p$ ]
        end for
    end while

end
```

Figure 16: Computation of a set of pivot candidates PC and an \mathcal{R} -compatible ordering

Condition 2: by construction of the sets **Origin**[j], a variable x_i is inserted in **Origin**[j] immediately after x_i has been numbered; this only applies for the unmarked x_j . So, x_j is necessarily numbered after x_i .

- Is this assignment ordering \mathcal{R} -compatible?

The first variables are obviously those taken from \mathcal{R} (step 1). The other condition is a direct consequence of condition 2 above.

Complexity:

Both steps have the same structure: choose a new variable x_i , mark and number it, and for each of its (unmarked) direct descendants, do some $O(1)$ operations (during step 2, a constraint is added to PC which also requires $O(1)$). The overall time complexity is therefore

$$O\left(\sum_{i=1}^n (1 + |\Gamma^+(i)|)\right) = O(n + e)$$

where $\Gamma^+(i)$ is the set of the direct descendants from x_i .

Acknowledgements

I wish to thank the “CONSTRAINTS” team of the Computer Science Laboratory of Montpellier for their helpful advice, and the anonymous reviewers for their useful comments and suggestions. I also thank Anne Bataller and Pascal Jappy for polishing the English. They all helped improve this paper. This research was partially supported by the PRC-IA research project “CSP FLEX” of the CNRS.
